Why Model from 1st Principles?

- Access to structural details that are difficult or impossible (e.g. In vivo versus in vitro, etc.) to explore with experiments.
- Enables predictive capabilities (as opposed to empirical models)
- Also:
 - Relatively cheap
 - Enables evaluation of design alternatives
 - Enables new application development
 - Enables intense analysis of promisory designs (thermodynamical and mechanical)
 - Reduces time to development
 - Enables development of novel engineering methods at the nanoscale

Nanotechnology and Nanoscience

Nanotechnology Definition

"It would be, in principle, possible (I think) for a physicist to synthesize any chemical substance that the chemist writes down. . . . Put the atoms down where the chemist says, and so you make the substance."

- Richard Feynman, *There's Plenty of Room at the Bottom* (Caltech, APS talk, 1959).

Not "nano by accident"

Smaller than we've ever
manufactured

"The purposeful engineering of matter at
scales of less than 100 nanometers to
achieve size-dependent properties and
functions"

Not just "small;" "small and different"

Matthew Nordan,
Lux Research, 2005.

- o AKA: **Molecular Manufacturing**
- o **Shift in paradigm:** Bottom-up vs Top-down
- o **1 nm** = 1 billionth of a meter!

The Scale of Things – Nanometers and More

Labeled "nanotechnology" only if it involves all of the following:

1. Research and technology development at atomic, molecular or macromolecular levels, in length scale of approximately 1 - 100 nm range.
2. Creating and using structures, devices and systems that have novel properties and functions because of their small and/or intermediate size.
3. Ability to control or manipulate on the atomic scale.

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

What makes the nanoscale special?

1. Interfaces (SA/V)
2. Quantum effects
3. Thermal fluctuations
4. Discreteness of matter

Many material properties, including melting point, fluorescence, surface tension, electrical conductivity, magnetic permeability, and chemical reactivity change as a function of particle size!

These:

- Can lead to differences between nanosystems and bulk
- Can be exploited to generate whole new devices and phenomena
- Can pose challenges that require novel solutions

Jaramillo-Botero et al, Nanomedicine: A Systems Engineering Approach, Pan Stanford Publishing (World Scientific), Nov. 2008.

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Surface area (SA) to volume (V)

- A larger SA/V ratio as a function of entity size
 - Assume cube with side l , $V=l^3$ and $A=6l^2$ then $A/V=6/l$ increases for small l
 - In cells: surface must allow sufficient exchange to support contents, hence ratio limits size (e.g. Eukaryotic cell $\sim 5\text{--}100\mu\text{m}$)
 - Higher ratio leads to more surface available for reactions (e.g. in enzymes)

Jaramillo-Botero et al, Nanomedicine: A Systems Engineering Approach, Pan Stanford Publishing (World Scientific), Nov. 2008.

Nanosensores

COLOMBIA CIENTÍFICA

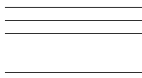

Quantum Effects

- Consider the energy levels of a metal as its size decreases
- 

bulk material

large nanoparticle

small nanoparticle
- Heisenberg's Uncertainty Principle: e.g. the more an electron is confined, the greater its momentum range, and vice versa
 - Quantum effects can yield a range of exploitable phenomena, e.g.:
 - Nanoscale gold particles selectively accumulate in tumors and the motion of their electrons is confined, which changes its optical response properties, so they can enable both precise imaging and targeted destruction of tumor
 - "Tunability of properties" implies that particle size can be used to fine-tune a material property of interest (e.g., changing fluorescence color in QD)
 - "Electron tunneling" have enabled STMs and flash memories

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Quantized energy states at atomic level

- Discrete quantum levels of a nanocluster may be tuned to modulate the electron transport, normally modulated by the pH, ions, and redox centers.
- Important Quantum effects include “electron tunneling” for STM, quantum Hall effect for resistance calibration instruments, spin polarization in MRI.
- Radiation induced processes such as photoisomerization in vision and photosynthesis in plants depend on quantum yield, which depends in turn on molecular structure.
- Novel optical and magnetic properties for nanometer scale devices potentially, useful for medical diagnosis or intervention.

Nanosensores

El futuro es de todos

Gobierno de Colombia

Quantized energy states at atomic level

Nanosensores

El futuro es de todos

Gobierno de Colombia

Thermal fluctuations

- Thermal fluctuations can be commensurate with size of nano-system

"For very small ferromagnetic (FM) particles the magnetic anisotropy energy (responsible for keeping the magnetization oriented in certain directions) is comparable to the thermal energy (kT). When this happens, the particles become *superparamagnetic*; as thermal fluctuations randomly flip the magnetization direction between parallel and antiparallel orientations. b. When the ferromagnetic nanoparticle is placed close to an antiferromagnetic (Anti-FM) surface the exchange bias interaction at the FM/Anti-FM interface provides additional anisotropy energy, which stabilizes the magnetization in one direction and prevents superparamagnetism."

Eisenmenger and Schuller, Nature Materials, 2003

Melting Temperature

Nanocrystal size decreases
↓
surface energy increases
↓
melting point decreases

e.g., 3 nm CdSe nanocrystal melts at 700 K compared to bulk CdSe at 1678 K

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Surface Discreteness

Once the size of an entity approaches that of its building blocks:

- Surfaces can no longer be assumed 'smooth' – they are ill-defined
 - long alkanes used as lubricants in macrosystems, but act as dirt in nm scale
 - vdW forces in conventional gears taken to the nano hinder normal operation

- Thermal fluctuations affect shape and structure
- Obscures bulk concepts as surface tension, dielectric constant, pH

Schrödinger's Electronic Wave Eq.

- Bohr's atomic model 1D i.e. one quantum number describes distribution of e- (n)
- Schrödinger's model allowed the electron to occupy 3D space (n, l, m).

Newton: "Where is/are the particle(s)?"

Schrodinger: "What is the probability distribution governing the positions?"

$$1 = \int P(R, t) dR = \int dR \psi^*(R, t) \psi(R, t) = \int dR |\psi(R, t)|^2$$

Erwin Schrödinger
(1887-1961)

Schrödinger first wrote down his "wave equation" during a skiing Christmas holiday in 1925-26

n: principal (integer): orbit size
l: azimuthal (angular momentum): orbit form
m_l: magnetic: orbit orientation
m_s: spin

$$\hat{H}\psi(R, t) = i\hbar\partial\psi(R, t)/\partial t$$

$$H(R)\psi(R) = E\psi(R)$$

$n=1, l=0, m=0$

$n=3, l=2, m=1$

$m=2$

$m=2$

COLOMBIA CIENTÍFICA

Molecular Mechanics and Dynamics

Why avoid the ideal calculation?

Two reasons:

1. Too hard or impossible. Exact solutions only exist for a reduced number of cases (H, harmonic oscillator, particle in a box, ...). For systems with a large number of electrons, no analytical solutions have been found (electron-electron repulsion).
2. Approximate solutions to the Schrödinger equation can sometimes work well and usually give more “insight” than the exact solutions (e.g. Hückel calculations).

These approximations form the base for what is known today as Molecular Mechanics/Dynamics Simulations.

Let's review them.

Approximations to Schrödinger's Equation

1. Born-Oppenheimer Approximation (1923)

- aka **Adiabatic Approximation**

- **Concept:**

- Nuclei are much heavier than electrons (H),
- Nuclei move in a much slower time scale than electrons.

$$\frac{M_{nuc}}{m_{el}} \approx 1,840$$

$$\frac{\omega_{el}}{\omega_{nuc}} \gg 1$$

- **Classical interpretation:**

- Nuclei interacting with electrons with spring-like forces leads to higher frequency oscillations of the light e's

- **Quantum interpretation:**

- For the time-dependent Schrödinger's equation we fix the nuclear geometry (at a particular time) and solve the e part of the total wavefunction

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Further Approximations that Lead to MM/MD

2. Nuclei moving as classical particles

- Since there are no explicit electronic contributions in the nuclear Schrödinger equation, it can be replaced by a Newtonian EOM
- **Introduces the idea of a Potential Energy Surface (PES)**

$$[K_n(R) + V_m(R) + E_{el}^{el}(R)]\psi^n(R) = E\psi^n(R) \rightarrow M \frac{\partial^2 R}{\partial t^2} = F \leftarrow F = -\frac{\partial}{\partial R} [V_m(R) + E_{el}^{el}(R)]$$

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Further Approximations that Lead to MM/MD

3. Approximate PES with analytical potentials

- Avoid solving a Schrödinger equation altogether, and
- ATOMS as classical particles (w/implicit electrons) moving on analytical PES

GROUND STATE

E as a function of nuclear positions only.

Bonded (valence) Interactions: spring-like interactions

	Description	Illustration	Typical Expressions	
			Energy (Potential)	Forces
"hard" DOF	Bond stretch		$U_r = \frac{1}{2} k_r (R - R_0)^2$	$-\frac{\partial U_r}{\partial R} = -k_r (R - R_0)$
	Bond Angle		$U_\theta = \frac{1}{2} k_\theta (\cos \theta - \cos \theta_0)^2$	$-\frac{\partial U_\theta}{\partial \theta} = k_\theta (\cos \theta - \cos \theta_0) \sin \theta$
Account (along with non-bond) for variations in structure and relative E	Torsion		$U_\phi = k_\phi [\cos(n\phi - d) + 1]$	$-\frac{\partial U_\phi}{\partial \phi} = k_\phi dn \sin(n\phi)$
	Inversion or Improper Torsion		$U_\psi = \frac{1}{2} k_\psi (\cos \psi - \cos \psi_0)^2$	$-\frac{\partial U_\psi}{\partial \psi} = k_\psi (\cos \psi - \cos \psi_0) \sin \psi$

Subindex 0 indicates rest value / K_r : Force constant (kcal/mol Å²) / K_θ : Rotational barrier (kcal/mol) / n : periodicity / d : phase factor

Nanosensores
Others: Cross-terms

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Bond-stretch

Simple Harmonic

$$E(R) = \frac{K_b}{2} (R - R_o)^2$$

$$R_o = 0.9 - 2.2 \text{ Å}$$

$$K_b = 700 \text{ (Kcal/mol)/Å}^2$$

Units: multiply by 143.88 to convert mdynes/Å to (Kcal/mol)/Å²

Morse

$$E(R) = D_o [e^{-\alpha(R-R_o)} - 1]^2$$

D_o is the bond energy in Kcal/mol
 R_o is the equilibrium bond distance

$$\alpha = \sqrt{K_b / 2D_o}$$

Morse scaling parameter, which
Most programs calculate from K_b and D_o

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Angle bend

Cosine Harmonic

$$E(\theta) = 1/2C[\cos(\theta) - \cos(\theta_0)]^2$$

Where the force constant is the second Derivative evaluated at the equilibrium angle

$$K_\theta = C \sin^2 \theta_0$$

Input parameters are always in terms of The force constant K_θ . In general

$$K_q = \left. \frac{\partial^2 E(q)}{\partial q^2} \right|_{q=q_0}$$

Cosine Periodic

$$E(\theta) = C[1 - B(-1)^N \cos(N\theta)]$$

This is particularly useful for organometallic systems where N=4 might be used for an Octahedral complex and N=3 might be used for a trigonal center. The parameter B is Either :

B = +1 (leading to a minimum for the linear geometry)
B = -1 (leading to a maximum for the linear geometry)

The periodicity N can be N = 1, 2, 3, ..., 6

The constant C is related to the force constant as $K_\theta = N^2 C$

The input is in terms of K_θ , N and B

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTIFICA

Torsions

Given any two bonds IJ and KL attached to a common bond JK

$$E(\phi) = \sum_{n=1}^p 1/2[k_n(1 - d\cos(n\phi))]$$

Where each k_n is in kcal/mol, $n = 1, \dots, 6$ is the periodicity of the potential and $d = \pm 1$ is the phase factor.

$d = +1$ the cis conformation is the minimum

$d = -1$ the cis conformation is the maximum

Input data is K and d for each n. Two modes:

- All torsions (nine for ethane). K is re-scaled for Dreiding and CHARMM force field
- MM2 and Amber K is not re-scaled.
- If USE ALL is turned OFF the program uses only the FIRST non-zero torsion for JK without re-scaling

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTIFICA

Improper Torsions

In the CHARMM and Dreiding-I force fields, inversion is defined as if it were a torsion.

$$E(\phi) = 1/2 K_{\phi} [\phi - \phi_o]^2$$

For a tetrahedral carbon atom with equal bonds this angle is 35.264 Degrees. For non-zero equilibrium angle $E(+\phi) \neq E(-\phi)$

This can be used to advantage for enforcing a particular stereochemistry

Improper Torsion
 ϕ is the angle between
 The IJK plane and the
 LJK plane

COLOMBIA CIENTÍFICA

Hydrogen Bonds Conventionally calculated via a pair wise interaction + 3 body angle term

$$E_{HB}(R, q_{AHD}) = E_b(R) E_a(\cos(q_{AHD}))$$

Bond terms:

$$\text{LJ12-10: } E_b(R_{AD}) = AR_{AD}^{-12} - BR_{AD}^{-10} = D_e \left[5 \left[\frac{R_e}{R_{AD}} \right]^{12} - 6 \left[\frac{R_e}{R_{AD}} \right]^{10} \right]$$

$$\text{Morse: } E_b(R_{AD}) = D_e [\chi^2 - 2\chi]$$

$$\chi = e^{-\alpha(R_{AD} - R_e)} = e^{-\frac{\gamma}{2} \left(\frac{R_{AD}}{R_e} - 1 \right)}$$

R_e is the equilibrium distance between **acceptor (A)** and **donor (D)**, A-D, and D_e is the energy well depth.

Angle terms:

$$E_a(\cos(q_{AHD})) = \cos(q_{AHD})^4$$

Hydrogen bonds:

- Account for unique water properties
- hold the 2 strands of DNA double helix together
- hold polypeptides together in secondary structures;
- help enzymes bind to their substrate;
- help antibodies bind to their antigen
- help transcription factors bind to each other;
- help transcription factors bind to DNA

Summary: From QM to MM/MD

Schrodinger equation:

$$H_T \Psi(r, R) = E_T \Psi(r, R)$$

where $H_T = K_n + K_e + V(r, R)$

Born-Oppenheimer approximation:

$$\Psi(r, R) = \psi(r, R) \Theta(R)$$

Equation of motion for electrons:

$$(K_e + V) \psi(r, R) = E_e(R) \psi(r, R)$$

Equation of motion for nuclei (motion on the PES)

Quantum: $[K_n + E_e(R)] \Theta(R) = E_T \Theta(R)$

Classical MD (Newtonian Mechanics): $m \frac{d^2 R}{dt^2} = -\nabla E_e(R)$

Force Field is needed to build up Potential Energy Surface (PES)

QM
PES
MM

Nanosensores

MM: Energy Minimization (EM)

- Purpose: find PE minima in a (hyper) surface
- Why?
 - Minimum points on the PES correspond to stable states (geometries or arrangement of atoms) of the system
- Applications:
 - Geometry optimization (static)
 - Conformation search (for highly populated structures)
 - Study the potential energy surfaces (dynamic)
 - Energy barriers between different conformers or
 - Steepness of a PES around a local minimum
- Keep in mind:
 - Non-trivial systems may have a very large number of minima on the PES (i.e. multidimensional function). Expensive.
 - (Usually) a global minima cannot be analytically guaranteed for non-trivial system (numerical solution) starting from an arbitrary conformation - not necessarily highly populated state

Nanosensores

COLOMBIA CIENTÍFICA

MM: Energy Minimization (EM)

- The minimization problem in molecular simulations can be stated as:
 - Given the QM or MM energy with the Cartesian or internal coordinates of the atoms $E(x_1, x_2, \dots, x_i)$ -> find the values of all x 's where E has a minimum value.
 - At a minimum point:

$$\frac{\partial E}{\partial \vec{x}} = 0; \quad \frac{\partial^2 E}{\partial \vec{x}^2} > 0$$

Eigenvalues of Hessian

- Temperature (=velocity) is zero (except SA)
- Only sample 1 system configuration

- We can obtain:
 - From gradient
 - Direction=where
 - Magnitude=steepness
 - Move atom in response to force to lower E
 - From Hessian
 - Curvature=direction change (minimum or stationary)

Most minimization methods move downhill to the nearest minimum

EM in MD

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Molecular Dynamics: Motivation

- **Very similar to physical experiments:**
 - Prepare a sample (N particle model)
 - Connect sample to measuring device (computer)
 - Let sample evolve under certain conditions (perform calculations)
 - Measure properties during time interval (equilibrate, then measure)
- **An Observable (A):** a function of particles position and momenta

$$A(p^N(t), r^N(t))$$
- Recall **EM** is used to determine time-independent, temperature-agnostic (velocity=0) minima in the PES, from which one can extract useful properties (limited small systems)
- But, how do we determine a **correct** initial “atomistic” configuration for a system that could compare reasonably to the “macroscopic” ones from experiments, let alone perform dynamics using what we know from MM?

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Molecular Dynamics: Motivation

- From statistical mechanics (Boltzmann and Gibbs):
 - Average values are defined as ensemble averages. Replace a single system evolving in time with a large number of replications of the system that are considered concurrently, i.e.

$$\langle A \rangle_{ensemble} = \int \int dp^N dr^N A(p^N(t), r^N(t)) \rho(p^N, r^N)$$

This is hard and expensive ! Involves 6N integrals (r,p)

Probability density $\rho(p^N, r^N) = \frac{1}{Q} \exp \left[\frac{-H(p^N, r^N)}{k_B T} \right]$

Partition function $Q = \int \int dp^N dr^N \exp \left[\frac{-H(p^N, r^N)}{k_B T} \right]$

- From The *Ergodic hypothesis*, replace an ensemble average (expectation value) by the time average, i.e.

$$\langle A \rangle_{time} = \langle A \rangle_{ensemble}$$

Much easier to compute the time average, so if we let the system evolve in time indefinitely it should eventually pass through all possible states !!

$$A_{time} = \lim_{\tau \rightarrow \infty} \frac{1}{\tau} \int_{t=0}^{\tau} A(p^N(t), r^N(t)) dt$$

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

When to use EM and when to use MD?

Recall, we can use MM-EM:

- To determine stable configuration states of a single system.
- To determine 0K properties of a single system configuration.
- To calculate normal modes and vibrational modes of a system.
- To calculate relative energies and transition states/structures.
- To calculate IR-spectra, IV or NMR-spectra.
- To compute single-component system properties ...

MD:

- To sample the conformational space of a system at $T > 0K$.
- To model temperature and pressure effects.
- To obtain thermodynamics and time-dependent (kinetic) properties.
- To compute multi-component system properties ...

Nanosensores

MD: Applications

- **Liquids:** phase transitions, viscosity, heat flow, multicomponents
- **Defects:** propagation, interstitials, grains, dislocations (point-linear-planar)
- **Fracture:** propagation, initiation, evolution, speed
- **Surfaces:** roughness, diffusion, melting, faceting
- **Friction:** tribology, adhesion
- **Clusters:** melting, role of surface and anisotropy, catalysis
- **Spectra:** scattering
- **Biomolecules:** protein, nucleic acids, membranes - conformation, free energy, surface free energy
- **Transport properties:** phase transitions, phonons, thermoelectrics
- **Non-equilibrium phenomena:** plasmas, combustion, turbulent flow,...
- **Limitations ...**
 - Transferability
 - As good as the force field
 - Light atoms (not He, Ne, H₂)
 - No excited states
 - Time (e.g. enough to reach equilibrium or detect infrequent events, i.e. longer than relaxation time of quantities of interest)

Simulation Ensembles

IF

nVE=constant:

GIVES

- **Microcanonical ensemble.** Total energy and volume controlled. Free run, no velocity or pressure scaling. Requires PBC for solvated simulations.

nVT=constant:

- **Canonical ensemble.** T controlled through random perturbations on atoms per step to simulate interaction with a heat bath [Andersen, 1980], velocity rescaling to maintain kinetic temperature, or adding friction terms.

nPT=constant:

- **Isobaric ensemble.** P controlled via changes in system volume to match desired pressure (scale positions and boundaries by factor).

(μ)VT=constant:

- **Grand-canonical ensemble.** N is allowed to fluctuate. Closely represents experimental conditions, gives direct access to the equation of state.

Jaramillo-Botero y Marmolejo, 2019

Important Properties of Interest

- Energy (internal)

$$U = \langle E \rangle = \frac{1}{M} \sum_{i=1}^M E_i$$

- Temperature

$$T(t) = \sum_{i=1}^N \frac{m_i v_i^2(t)}{K_B N_{dof}} = \sum_{i=1}^N \frac{|p_i(t)|^2}{m_i K_B N_{dof}}$$

- Pressure

$$P = \frac{1}{V} \left[N K_B T - \frac{1}{3} \sum_{i=1}^N \sum_{j=i+1}^N r_{ij} f_{ij} \right]$$

- Heat Capacity

$$C_V = \left(\frac{\partial U}{\partial T} \right)_V = \langle (E - \langle E \rangle)^2 \rangle / K_B T$$

Biosensors

Generalities

- A biosensor is an analytical device, used for the detection of a chemical substance, that combines a biological component with a physicochemical detector.
- The transducer or the detector element, which transforms one signal into another one, works in a physicochemical way, resulting from the interaction of the analyte with the biological element, to easily measure and quantify.

Biotransducer

- Biosensors can be classified by their biotransducer type.
- The most common types of biotransducers used in biosensors are:
 - Electrochemical biosensors
 - Optical biosensors
 - Electronic biosensors
 - Piezoelectric biosensors
 - Gravimetric biosensors
 - Pyroelectric biosensors

Opportunities

- There are many opportunities in the sensing field for detecting and measuring very low analyte concentrations.
- Sub-picomolar detection limits represent useful concentration ranges for the detection of many disease biomarkers.

Nanosensores

El futuro es de todos

Gobierno de Colombia

COLOMBIA CIENTÍFICA

Challenges

- Achieving sub-picomolar detection limits has three major challenges:
 1. **Assay sensitivity**
 - One strategy to gain greater sensitivity involves confining the sensing volume to the nanoscale, as used in nanopore- or nanoparticle- based sensors
 2. **Response time**
 - Methods to improve response time typically focus on obtaining an intimate mixture between the sensor and the sample either by extending the length scale of nanoscale sensors using nanostructuring or by dispersing magnetic nanoparticles through the sample to capture the analyte
 3. **Selectivity (including limiting background signals).**
 - One solution to help address the challenge of selectivity is loading nanoparticles with many biorecognition species is

Band structures

- The band structure of a material determines its electronic and optical properties.
- Band structure calculations require solving the Schrödinger equation using particle wave functions in a periodic potential:
 - $\psi_{nk}(r) = \exp(ikr)u_{nk}(r)$
 - where $\psi(r)$ is an eigenfunction of the system and is defined as the product of a plane wave envelope and a periodic Bloch function $u(r)$; n corresponds to the band index, while k corresponds to the wave vector associated with the direction of motion of the electron in the crystal and takes on values within the corresponding Brillouin zone.
- The band structure is determined by the orbital energies ε_{nk} for each band n and momentum k .

Band structure diagrams

- Solving the one-electron Schrödinger equation gives energy eigensolutions.
- We continue with the other allowed values of k .

David Miller, "Quantum Mechanics for Scientists and Engineers", Stanford Online (2016).

Nanosensores

Band structure diagrams

- A larger crystal gives more allowed values of k .
- This sets of "dots" effectively become like lines.
 - We refer to the group of dots on a line as a "band".

David Miller, "Quantum Mechanics for Scientists and Engineers", Stanford Online (2016).

Nanosensores

Band structure diagrams

- There are multiple bands in a band structure, in fact, an infinite number, but usually only a few are important for the properties of a material.
- In each band, we only have to plot k -values from $-\pi/a$ to π/a .
- This range is known as the (first) Brillouin zone.

David Miller, "Quantum Mechanics for Scientists and Engineers", Stanford Online (2016).

Nanosensores

Semiconductors and insulators

- Semiconductors and insulators have an (almost) completely full band (the valence band) separated by a "bandgap" of energy E_G from an (almost) completely empty band (the conduction band).

David Miller, "Quantum Mechanics for Scientists and Engineers", Stanford Online (2016).

Nanosensores

Metals

- Because of the number of electrons in the metal atoms, the lowest conduction band is partially full of electrons.
 - e.g., half-full even at zero temperature.
 - Hence metals conduct electricity well.

David Miller, "Quantum Mechanics for Scientists and Engineers", Stanford Online (2016).

Nanosensores

Brillouin zone in 3D

- The Brillouin zone for the diamond or zinc-blende lattice is a 3D object.
 - Two important directions are:
 - X: Along one of the coordinate directions.
 - L: Along one of the cube space diagonals.
 - The center is the Γ (gamma) point.

David Miller, "Quantum Mechanics for Scientists and Engineers", Stanford Online (2016).

Nanosensores

Brillouin zone in 3D

- Typically, the band structure is calculated only along a few directions.
- Such as along the lines from the Γ point (at the center of the Brillouin zone) to the X point and the L point.

Hands-on tutorials

DFT calculations with Quantum ESPRESSO

- We will begin our test calculations using the online tool:
<https://nanohub.org/tools/dftqe>
- This tool allows us to run quantum ESPRESSO (a powerful electronic structure code based on density-functional theory, plane waves, and pseudopotentials) for performing several calculations:
 - Total energy.
 - Energy minimization to predict structures.
 - Kohn-Sham band structure of periodic systems and phonons.
 - Cell and force relaxation.
 - Output of Stress and forces.

Silicon Band Structure

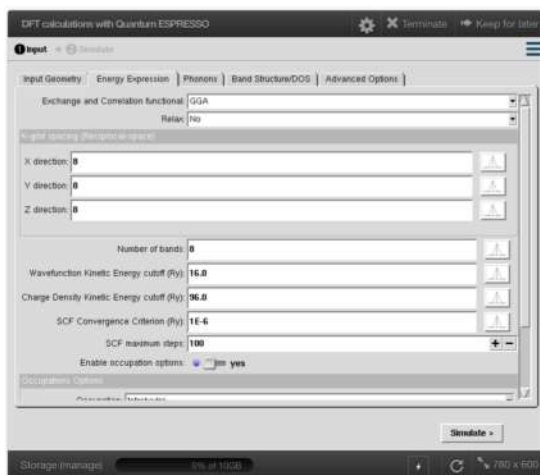

- The tool already has some premade atomistic structures with their corresponding cell parameters and atom coordinates.

- Choose Si diamond.

Nanosensores

Silicon Band Structure

- We can choose LDA or GGA functionals and enable/disable relaxation.
- Choose GGA and no relaxation, but you should also explore the other options.
- Specify k-points in the reciprocal space, as well as other calculation parameters.
- We will use default values for the moment.

Nanosensores

Silicon Band Structure

- Enable Band Structure Calculation, choose the path along the high-symmetry points you wish to explore and the number of k-points along the path.
- Notice your path goes from $L(0.5, 0.5, 0.5)$ to $\Gamma(0.0, 0.0, 0.0)$ to $X(1.0, 0.0, 0.0)$.

GNR Band Structure

- Since the GNR is only periodic on the z-direction, we only increase the number of k-points on that direction.
 - The number of k-points in the other directions is set to 1.
- Type in the number of bands.
 - Remember carbon has 4 Valence electrons and hydrogen just 1.

GNR Band Structure

- We are interested in computing the band structure along the transport direction (z-direction).
 - Then, the path goes from $Z(0.0, 0.0, 0.5)$ to $\Gamma(0.0, 0.0, 0.0)$ to $Z(0.0, 0.0, 0.5)$.

GNR Band Structure

- Notice the calculation could take several minutes on a single core.
- You may want to request a multi-core simulation and speedup the calculation.

GNR Band Structure

- We can zoom in around the Fermi energy and measure the bandgap of our AGNR.
- In this case, we get a direct gap of $\sim 0.35\text{eV}$.

GNR Density of States

- We can also get the Density of States (DOS) of our AGNR.
- How can we relate this to the band structure?

Electrical Conduction through a molecule

- We can also use nanohub's tools for computing electrical conduction through a molecule:
<https://nanohub.org/resources/molctoy>
- This tool computes current-voltage (I-V) characteristics and conductance spectrum (G-V) of a molecule sandwiched between two metallic contacts.
